Thymic epithelial tumors (TETs) represent one of the most common epithelial neoplasms of the thorax. Preclinical research suggests that TETs contain a range of highly sensitive and resistant TET cell subsets. The use of sensitive imaging techniques to monitor responses to therapy is confounded by the heterogeneous nature of TETs and the presence of multiclonality, with only select clonal subpopulations of cells responding to therapy. A noninvasive molecular imaging technology, the diffusion-weighted magnetic resonance imaging (DWI), is under development for TETs. The availability of a standardized and validated DWI protocol in humans with TETs could allow for concurrent clinical and molecular imaging of TETs. In this project we will: 1) characterize the sensitivity and reproducibility of the DWI technique on patient-derived fresh TET specimens; 2) evaluate the relationship between DWI signal and tumor cellularity, vascularity and composition of tumor cells and stroma; 3) apply the technique to evaluate the clinical response to therapy; and 4) assess the ability of DWI to distinguish TETs from other thoracic lesions. Using the results of the proposed research we will be prepared to submit an R01 to collect preliminary data for an eventual multicenter clinical trial. Q. Maximum Likelihood Estimation for Continuous Random Variable. I want to find MLE for a continuous random variable, using the following information: We observe the sample $\{X_i\}$ with size N . $X_i \sim N(0, \sigma_x^2)$ $Y_i \sim N(0, \sigma_y^2)$ Is this correct? A: I assume you mean X and Y are continuous. I think you are right, but I have to say the question is confusing.
$$X = \frac{1}{\sqrt{N}} \sum_{i=1}^N \sigma_x X_i$$
